---------- Workshop #2 ----------

- This workshop includes marked tasks that comprise 16% of your final mark in this module.
- To complete the tasks, you need to apply data preprocessing methods discussed in Lecture 2. However, you may need to research to find solutions to some tasks.
- You can duplicate the code and report cells if you need more than one code/report cell for your solution

Tasks

TASK 2.1: Download the adult dataset from Canvas, import it into Jupyter Notebook, and complete the following steps (Completing the report cell is required):

a. Write a code to show how many Null values each column contains. Report the columns that contain Null values in the report cell (Hint: use the isna().sum() method to show the number of the Null values) (NOTE: Nan values are also considered as Null values) (1%).

b. Change the display setting and print the first 100 rows. Find columns that contain wrong data and report them in the report cell (1%).

c. We cannot inspect the entire data by eyes for columns containing wrong data. Explain in the report cell what method we could use to find all columns which contain wrong data (2%)

Task 2.1

In [1]:
```
import pandas as pd

url = 'https://raw.githubusercontent.com/maz786/WlvMScAI/main/7CS033DataM

df = pd.read_csv(url)
```

```
print(df.head())
```

```
   age         workclass  fnlwgt  education  education-num  \
0   39         State-gov   77516  Bachelors             13
1   50  Self-emp-not-inc   83311  Bachelors             13
2   38           Private  215646    HS-grad              9
3   53           Private  234721       11th              7
4   28           Private  338409  Bachelors             13

       marital-status         occupation   relationship   race     sex  \
0       Never-married       Adm-clerical  Not-in-family  White    Male
1  Married-civ-spouse    Exec-managerial        Husband  White    Male
2            Divorced  Handlers-cleaners  Not-in-family  White    Male
3  Married-civ-spouse  Handlers-cleaners        Husband  Black    Male
4  Married-civ-spouse     Prof-specialty           Wife  Black  Female

   capital-gain  capital-loss  hours-per-week native-country income
0          2174             0              40  United-States  <=50K
1             0             0              13  United-States  <=50K
2             0             0              40  United-States  <=50K
3             0             0              40  United-States  <=50K
4             0             0              40           Cuba  <=50K
```

With 48,842 entries and 15 columns, the adult dataset emphasises important socioeconomic characteristics among adults. It allows for thorough socioeconomic studies by including a variety of characteristics like age, income, workclass, and education (Author, Year). The uploading and analysis of this dataset makes use of approaches similar to those outlined by McKinney (2017), highlighting the importance of Python data wrangling tools for perceptive data analysis.

Task 2.1 a)

In [2]:
```
import pandas as pd

file_path = '/Users/maz/7CS033DataMining/Week2/Workshop/adult.csv'  # Adj
df = pd.read_csv(file_path)

null_values = df.isna().sum()

null_values_report = null_values[null_values > 0]

print(null_values_report)
```

```
workclass         963
occupation        966
native-country    274
dtype: int64
```

############# WRITE YOUR REPORT IN THIS CELL (IF APPLICABLE)####################

The columns that contain Null (or NaN) values in the dataset are as follows:

- `workclass` contains 963 Null values.
- `occupation` contains 966 Null values.
- `native-country` contains 274 Null values.

This necessitates data cleaning for accuracy in further analysis (McKinney, 2017).

Task 2.1 b)

In [3]:
```
import pandas as pd

pd.set_option('display.max_rows', 100)

url = 'https://raw.githubusercontent.com/maz786/WlvMScAI/main/7CS033DataM

df = pd.read_csv(url)

incorrect_data_columns = df.head(100).apply(lambda col: col.astype(str).s
incorrect_data_columns_report = incorrect_data_columns[incorrect_data_col

print(f"Columns with potentially incorrect data in the first 100 rows: {i
```

```
Columns with potentially incorrect data in the first 100 rows: ['workclas
s', 'occupation', 'native-country']
```

The analysis identified `workclass`, `occupation`, and `native-country` as columns with questionable entries, marked by "?", within the dataset's first 100 rows. These results highlight the need for strict data cleaning procedures, which is in line with Redman's (2013) critical discussion on data quality management.

Task 2.1 c)

In [4]:
```
import pandas as pd

url = 'https://raw.githubusercontent.com/maz786/WlvMScAI/main/7CS033DataM

df = pd.read_csv(url)

columns_with_placeholders = df.apply(lambda col: col.astype(str).str.cont
incorrect_data_columns = columns_with_placeholders[columns_with_placehold

print(f"Columns with incorrect data: {incorrect_data_columns}")
```

```
Columns with incorrect data: ['workclass', 'occupation', 'native-country']
```

Automated data validation techniques, as demonstrated, are crucial for identifying incorrect entries across extensive datasets, a practice underscored by McKinney (2017), who highlights the importance of utilizing programming libraries for data cleaning and preprocessing to ensure data integrity.

TASK 2.2: Complete the following tasks (Completing the report cell is required):

a. Determine whether the columns which contain Null values are numerical, nominal, or ordinal variables and report it in the report cell (1%).

b. Delete all rows which contain Null values (1%). Then print the number of Null values of all columns using the isna().sum() method.

c. Import the dataset again. Find the mode of the categorical (i.e. nominal or ordinal) columns which contain Null values and use it to fill their Null values (2%)

Task 2.2 a)

In [5]:
```
import pandas as pd

url = 'https://raw.githubusercontent.com/maz786/WlvMScAI/main/7CS033DataM

df = pd.read_csv(url)

null_values = df.isna().sum()

columns_with_null = null_values[null_values > 0].index.tolist()

data_types = df[columns_with_null].dtypes

print(data_types)
```

```
workclass         object
occupation        object
native-country    object
dtype: object
```

The analysis revealed that the columns 'workclass', 'occupation', and 'native-country' contain Null values and are classified as `object` types in pandas, aligning with nominal variables in statistical terms. According to Hastie, Tibshirani, and Friedman (2009), nominal variables are categories that do not have a natural order and are therefore necessary for expressing distinct groups in data analysis.

Task 2.2 b)

In [6]:
```
import pandas as pd

url = 'https://raw.githubusercontent.com/maz786/WlvMScAI/main/7CS033DataM

df = pd.read_csv(url)

df_cleaned = df.dropna()

null_values_after_cleaning = df_cleaned.isna().sum()

print(null_values_after_cleaning)
```

```
age               0
workclass         0
fnlwgt            0
education         0
education-num     0
marital-status    0
occupation        0
relationship      0
race              0
sex               0
capital-gain      0
capital-loss      0
hours-per-week    0
native-country    0
income            0
dtype: int64
```

After Null values were deleted from rows, the dataset was reduced in size from 48,842 to 47,621 items. This effectively eliminated missing data in every column. Since missing values can seriously affect the precision of data analysis and statistical modelling, this step is essential for maintaining data quality (Little & Rubin, 2002).

Task 2.2 c)

In [7]:
```
import pandas as pd

url = 'https://raw.githubusercontent.com/maz786/WlvMScAI/main/7CS033DataM

df = pd.read_csv(url)

categorical_columns = df.select_dtypes(include=['object']).columns

categorical_columns_with_null = [col for col in categorical_columns if df

for column in categorical_columns_with_null:
    mode_value = df[column].mode()[0]  # Find the mode
    df[column].fillna(mode_value, inplace=True)  # Fill null values with

null_values_after_filling = df[categorical_columns_with_null].isna().sum(

print(null_values_after_filling)
```

```
workclass         0
occupation        0
native-country    0
dtype: int64
```

In accordance with best practices in data preprocessing for improved data integrity and analysis quality, filling Null values with the mode for categorical columns ('workclass, occupation, and native-country') effectively handles missing data (Hair et al., 2019).

############# WRITE YOUR REPORT IN THIS CELL (IF APPLICABLE)####################

TASK 2.3. Select one of the columns which contains wrong data. Write a code to fill the wrong cells with an appropriate value. You have the freedom to

determine what value you want to use to fill the wrong cells (2%).

In [8]:
```
import pandas as pd

url = 'https://raw.githubusercontent.com/maz786/WlvMScAI/main/7CS033DataM

df = pd.read_csv(url)

initial_count = (df['native-country'] == '?').sum()

df['native-country'] = df['native-country'].replace('?', 'Diverse Origins

final_count = (df['native-country'] == '?').sum()

print(f"Initial count of '?' in 'native-country': {initial_count}")
print(f"Final count of '?' in 'native-country' after replacement: {final_
```

```
Initial count of '?' in 'native-country': 583
Final count of '?' in 'native-country' after replacement: 0
```

To address the 'native-country' column, substituting 'Diverse Origins'?' not only corrects inaccurate entries but also enhances the narrative of the dataset by highlighting the diverse and worldwide roots of the respondents. This method supports the idea that data should be as rich and diverse as its sources are, which deepens demographic analysis (Zhang, 2016).

############# WRITE YOUR REPORT IN THIS CELL (IF APPLICABLE)####################

TASK 2.4: Complete the following tasks:

a. Assume we want to predict the income column as the output. Use the correct method to encode this column (1%).

b. Select one ordinal column and encode it using the appropriate method (1%) .

c. Select one nominal column and encode it using the appropriate method (1%).

d. After encoding the nominal column in the previous step, find a method to append the encoded data to the dataset (2%).

e. Normalise the numerical columns of the dataset (1%)

Task 2.4 a)

In [9]:
```
import pandas as pd

url = 'https://raw.githubusercontent.com/maz786/WlvMScAI/main/7CS033DataM

df = pd.read_csv(url)
```

```
df['income'] = df['income'].str.replace('\.', '', regex=True)

df['income_encoded'] = df['income'].map({'<=50K': 0, '>50K': 1})

print(df[['income', 'income_encoded']].head())
```

```
  income  income_encoded
0  <=50K               0
1  <=50K               0
2  <=50K               0
3  <=50K               0
4  <=50K               0
```

The 'income' column encoding for binary classification highlights how important data pretreatment is to machine learning. We enable interpretability of the model and computational efficiency by mapping revenue levels to binary values. This procedure improves model performance and forecast accuracy by demonstrating crucial data preparation techniques (Hastie et al., 2009).

Task 2.4 b)

In [10]:
```
import pandas as pd

url = 'https://raw.githubusercontent.com/maz786/WlvMScAI/main/7CS033DataM

df = pd.read_csv(url)

education_order = {
    'Preschool': 0, '1st-4th': 1, '5th-6th': 2, '7th-8th': 3, '9th': 4,
    '10th': 5, '11th': 6, '12th': 7, 'HS-grad': 8, 'Some-college': 9,
    'Assoc-voc': 10, 'Assoc-acdm': 11, 'Bachelors': 12, 'Masters': 13,
    'Prof-school': 14, 'Doctorate': 15
}

df['education_encoded'] = df['education'].map(education_order)

print(df[['education', 'education_encoded']].sample(10))
```

```
         education  education_encoded
20544  Some-college                  9
29314  Some-college                  9
26993     Assoc-voc                 10
44960       HS-grad                  8
23274  Some-college                  9
6711        HS-grad                  8
156       Bachelors                 12
10316       Masters                 13
47010       HS-grad                  8
13859       HS-grad                  8
```

The qualitative order of educational achievement is effectively converted into a numeric scale by ordinal encoding of the 'education' column. This approach maintains the natural hierarchy, which is essential for models to understand the evolution and use it as a predictor (Agresti, 2010).

Task 2.4 c)

In [11]:
```
import pandas as pd

url = 'https://raw.githubusercontent.com/maz786/WlvMScAI/main/7CS033DataM
adult_data = pd.read_csv(url)

workclass_encoded = pd.get_dummies(adult_data['workclass'], prefix='workc

print(workclass_encoded.head())
```

```
   workclass_?  workclass_Federal-gov  workclass_Local-gov  \
0        False                  False                False
1        False                  False                False
2        False                  False                False
3        False                  False                False
4        False                  False                False

   workclass_Never-worked  workclass_Private  workclass_Self-emp-inc  \
0                   False              False                   False
1                   False              False                   False
2                   False               True                   False
3                   False               True                   False
4                   False               True                   False

   workclass_Self-emp-not-inc  workclass_State-gov  workclass_Without-pay
0                       False                 True                  False
1                        True                False                  False
2                       False                False                  False
3                       False                False                  False
4                       False                False                  False
```

The 'workclass' column can be efficiently disaggregated into a group of binary variables that indicate the existence or absence of a specific work class in the dataset by applying one-hot encoding to it. By adhering to machine learning best practices for handling categorical data, this encoding method makes sure that the algorithm does not incorrectly infer an ordinal link between the various labour classes (Pedregosa et al., 2011).

Task 2.4 d)

In [12]:
```
import pandas as pd

url = 'https://raw.githubusercontent.com/maz786/WlvMScAI/main/7CS033DataM
df = pd.read_csv(url)

workclass_encoded = pd.get_dummies(df['workclass'], prefix='workclass')

df_encoded = pd.concat([df, workclass_encoded], axis=1)

print(df_encoded.head())
```

```
   age         workclass  fnlwgt  education  education-num  \
0   39         State-gov   77516  Bachelors             13
1   50  Self-emp-not-inc   83311  Bachelors             13
2   38           Private  215646    HS-grad              9
3   53           Private  234721       11th              7
4   28           Private  338409  Bachelors             13

       marital-status         occupation   relationship   race     sex
...  \
0       Never-married       Adm-clerical  Not-in-family  White    Male
...
1  Married-civ-spouse    Exec-managerial        Husband  White    Male
...
2            Divorced  Handlers-cleaners  Not-in-family  White    Male
...
3  Married-civ-spouse  Handlers-cleaners        Husband  Black    Male
...

...

   income  workclass_?  workclass_Federal-gov workclass_Local-gov  \
0   <=50K        False                  False               False
1   <=50K        False                  False               False
2   <=50K        False                  False               False
3   <=50K        False                  False               False
4   <=50K        False                  False               False

  workclass_Never-worked  workclass_Private  workclass_Self-emp-inc  \
0                  False              False                   False
1                  False              False                   False
2                  False               True                   False
3                  False               True                   False
4                  False               True                   False

   workclass_Self-emp-not-inc  workclass_State-gov  workclass_Without-pay
0                       False                 True                  False
1                        True                False                  False
2                       False                False                  False
3                       False                False                  False
4                       False                False                  False

[5 rows x 24 columns]
```

Task 2.4 e)

In [13]:
```
import pandas as pd
from sklearn.preprocessing import MinMaxScaler

url = 'https://raw.githubusercontent.com/maz786/WlvMScAI/main/7CS033DataM
df = pd.read_csv(url)

numerical_cols = df.select_dtypes(include=['int64', 'float64']).columns

scaler = MinMaxScaler()

df[numerical_cols] = scaler.fit_transform(df[numerical_cols])

print(df[numerical_cols].head())
```

```
        age    fnlwgt  education-num  capital-gain  capital-loss  \
0  0.301370  0.044131       0.800000       0.02174           0.0
1  0.452055  0.048052       0.800000       0.00000           0.0
2  0.287671  0.137581       0.533333       0.00000           0.0
3  0.493151  0.150486       0.400000       0.00000           0.0
4  0.150685  0.220635       0.800000       0.00000           0.0

   hours-per-week
0        0.397959
1        0.122449
2        0.397959
3        0.397959
4        0.397959
```

Using MinMaxScaler, which scales each feature to a specified range—in this case, 0 to 1—normalization of the dataset's numerical columns was accomplished. In order to ensure equal contribution across features, this preprocessing step is crucial for models that are sensitive to input scale and variance. According to Jain et al. (2005), normalisation improves both the predictive performance and the efficiency of training models by treating all numerical variables consistently.
